Catheter ablation is a treatment for cardiac arrhythmias. During ablation, a doctor inserts a catheter (thin, flexible tube) into the heart. A special machine delivers energy through the catheter to tiny areas of the heart muscle that cause the abnormal heart rhythm. This energy “disconnects” the pathway of the abnormal rhythm.

Nonpharmacologic therapy for symptomatic and life-threatening cardiac arrhythmias includes the use of catheter ablation, the implantable cardioverter-defibrillator for ventricular arrhythmias, and, at times, cardiac surgery. ## **UpToDate**

Radiofrequency (RF) catheter ablation depends upon the conversion of electrical energy to tissue heat that results in thermal injury and necrosis of the targeted arrhythmogenic tissue. Tissue heating results in damage to the sarcolemmal membrane, nonspecific poration, and calcium overload leading to cell death.

Catheter ablation is commonly used to treat supraventricular tachycardias (SVTs) such as those due to WPW (Wolff Parkinson White) syndrome which is an abnormal electrical connection between the top and bottom chambers (which some people are born with) which suddenly causes the heart to race; or AVNRT (AV node reentrant tachycardia) which is an arrhythmia involving the normal conduction system.

Catheter ablation is used to treat certain types of arrhythmias, or irregular heartbeats, that cannot be controlled by medicine or if you have a high risk for ventricular fibrillation (v-fib), sudden cardiac arrest, or atrial fibrillation. Cardiologists, or doctors who specialize in the heart, will perform catheter ablation in a hospital.

Abstract Aims: Catheter ablation is considered the treatment of choice for many tachyarrhythmias, but convincing 'real-world' data on efficacy and safety are lacking. Using Swedish national registry data, the ablation spectrum, procedural characteristics, as well as ablation efficacy and reported adverse events are reported.
