Reviewed in the United States on March 1, 2008. Direction Solidification of Steel Castings is the definitive book on solidificiation results based on the shape of the casting and risering and cooling conditions. The book is a summary of a large number of investigations carried out in a scientific manner. Robert Wlodawer was a foundry engineer who aimed to use the principles of Chvorinov and credited Chvorinov with being ahead of his time, in principles of solidification.

Last Modified Date: August 26, 2020. "Directional solidification" is a metal casting term. It refers to the process of controlled feeding of the molten metal into a temperature-controlled mold to produce a part that is free of hollow spots, called shrink defects. Directional solidification is also used to refine the metal during the casting process because the impurities found in the molten metal will continue to rise to the surface of the pool, following the path of least resistance as they ...

## **What is Directional Solidification?**

Directional solidification (DS) and progressive solidification are types of solidification within castings. Directional solidification is solidification that occurs from farthest end of the casting and works its way towards the sprue. Progressive solidification, also known as parallel solidification, is solidification that starts at the walls of the casting and progresses perpendicularly from that surface.

- Risers are reservoirs of liquid metal that feed extra metal to the mold to compensate for shrinkage
- Risers are designed to conserve metal □ Located so that directional solidification occurs from the extremities of the mold toward the riser □ Should feed directly to the thickest regions of the casting

The side feeder attached so that the casting is in the drag, as shown in the lowest diagram in Figure 5.20, produces favourable directional solidification. The influence of using a tapered feeder with the two acceptable systems in Figure 5.20 is shown in Figure 5.21. In both cases the final freezing position is moved closer to the feeder contact location.
